

Hello candidate,

Welcome to the next step of the recruitment process for the DWS Backend Team. Thank you for your interest in applying to join us and for the time and effort you're willing to dedicate for this test.

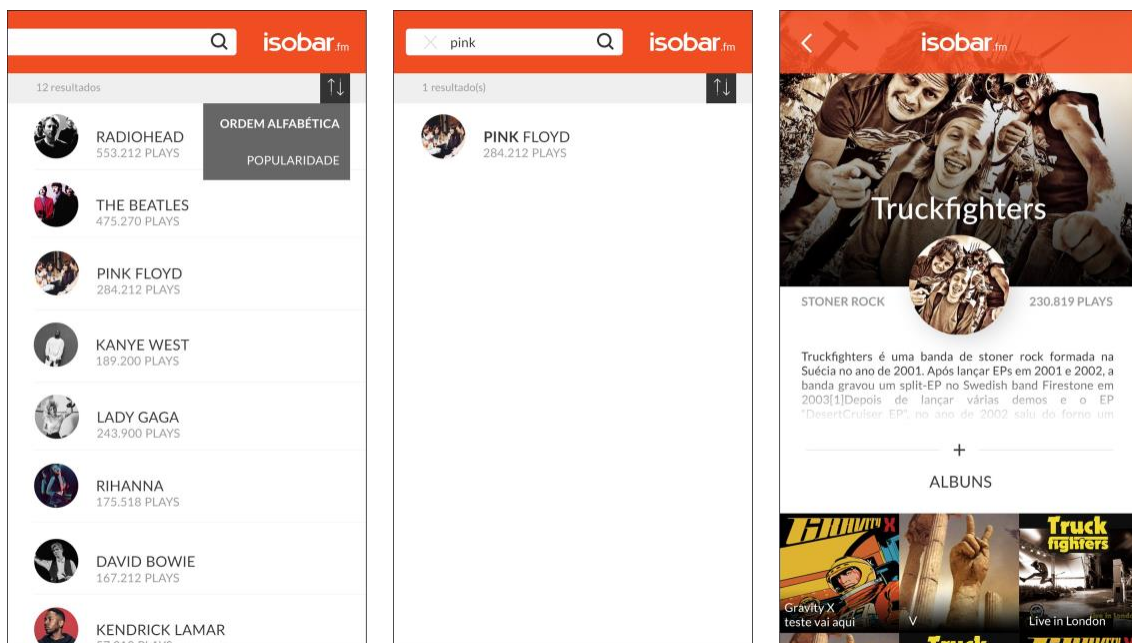

First of all, we don't expect you to finish everything we proposed here, we just want you to do your best and show us your skills. Our analysis will be based on the quality of your solution and the code you produce as well as your efficiency. After receiving this test, you are expected to deliver a working solution within 4 hours. This limit is imposed to make sure you are able to prioritize the core of the application and develop it accordingly, so focus on small increments of working features.

You must use a Java IDE to implement your solution and send us your code, like Eclipse, IntelliJ IDEA or Netbeans. Optionally, you can publish your application into a cloud server such as AWS, Heroku or whatever other option you feel willing to. Remember, it is OK doing this after the test time is over. So, ready to get your hands dirty?

isobar.fm

The project consists of creating a Java backend capable of interacting with third-party services and exposing a rest API which would be consumed by other platforms such as Android, iOS, WebServers and even other backend applications. The comps detailing the specific integrations and services are below, we ask you to follow those and develop the backend as a standalone application, focusing on maintainability, scalability and performance.

- Firstly, you must consume data from our endpoint and expose it through a REST API with endpoints that should serve at least, but not limited to, the app wireframes described below;
 - URL: <https://bands-api.vercel.app/api/bands>
- Secondly, you must implement a caching layer to optimize your API performance;

That's it! We wish you very good luck and happy coding.

DWS Team.
